In Brief

Geng et al. report the identification of a subset of human acute lymphoblastic leukemia (ALL) cases that critically depends on tonic pre-BCR signaling and is selectively sensitive to small molecule inhibitors of SYK and SRC tyrosine kinases downstream of the pre-BCR.

Highlights

- ALL can be divided into two distinct subtypes based on pre-BCR function
- Pre-BCR-induced activation of BCL6 further increased pre-BCR signaling output
- Pre-BCR inhibitors reduced BCL6 levels and selectively killed pre-BCR⁺ ALL cells
- BCL6 represents a biomarker to identify patients with pre-BCR⁺ ALL

SUMMARY

Studying 830 pre-B ALL cases from four clinical trials, we found that human ALL can be divided into two fundamentally distinct subtypes based on pre-BCR function. While absent in the majority of ALL cases, tonic pre-BCR signaling was found in 112 cases (13.5%). In these cases, tonic pre-BCR signaling induced activation of *BCL6*, which in turn increased pre-BCR signaling output at the transcriptional level. Interestingly, inhibition of pre-BCR-related tyrosine kinases reduced constitutive *BCL6* expression and selectively killed patient-derived pre-BCR⁺ ALL cells. These findings identify a genetically and phenotypically distinct subset of human ALL that critically depends on tonic pre-BCR signaling. In vivo treatment studies suggested that pre-BCR tyrosine kinase inhibitors are useful for the treatment of patients with pre-BCR⁺ ALL.

Significance

Recent work successfully introduced BCR signaling inhibitors into patient care for various subtypes of mature B cell lymphoma, for example, Ibrutinib (BTK) and Idelalisib (PI3K δ), for germinal center-derived B cell lymphoma. However, it is not known whether pre-BCR signaling represents a therapeutic target in pre-B ALL. Here we report the identification of a subset of human ALL cases that critically depends on tonic pre-BCR signaling and is selectively sensitive to small molecule inhibitors of SYK and SRC tyrosine kinases downstream of the pre-BCR.

INTRODUCTION

Bone marrow progenitor cells in mice produce approximately 10 million pre-B cells daily (Osmond, 1991), the vast majority of which is eliminated at the pre-B cell receptor (BCR) checkpoint (Sakaguchi and Melchers, 1986). Early pre-B cells are programmed to die unless they productively rearrange V_HDJ_H gene segments and are rescued by “tonic” pre-BCR signal activity into the long-lived pool of mature peripheral B cells (Rajewsky, 1996). Even in mature B cells, continuous tonic signaling from the BCR is required for B cell survival and maintenance and conditional ablation of tonic BCR signaling results in rapid B cell depletion (Kraus et al., 2004). Interestingly, however, loss of tonic BCR signaling can be rescued by activation of PI3K-AKT signaling (Srinivasan et al., 2009), identifying PI3K-AKT as a central survival pathway downstream of the (pre-BCR) BCR. Tonic pre-BCR signaling involves constitutive activity of the proximal pre-BCR-associated SRC family kinases LYN, FYN, and BLK (Saijo et al., 2003), as well as SYK and ZAP70 (Schweighoffer et al., 2003), which then activate PI3K (Guo et al., 2000; Okada et al., 2000). Recent work highlighted the particular importance of the PI3K p110 δ (PIK3CD) isoform for pre-BCR survival signaling during early B cell development (Ramadani et al., 2010). The discovery that most subtypes of B cell lymphoma critically depend on BCR signaling (Davis et al., 2010; Schmitz et al., 2012) has led to the development of new targeting strategies that focus on BCR signaling at the level of SRC kinases (Lyn, Fyn, and Blk), SYK/ZAP70 and PI3K δ (Burger and Okkenhaug, 2014; Chen et al., 2006, 2013; Cheng et al., 2011; Ke et al., 2009; Yang et al., 2008). In addition, small molecule inhibition of BTK, which mediates “chronic active BCR signaling” in activated B cell-like (ABC) diffuse large B cell lymphoma (DLBCL), chronic lymphocytic leukemia (CLL), and mantle cell lymphoma (MCL) has achieved major clinical success in the treatment of these diseases (Byrd et al., 2013a; Davis et al., 2010; Schmitz et al., 2012; Wang et al., 2013). While the role of BCR signaling in the biology and treatment has been elucidated in all major B cell lymphoma subtypes, the role of pre-BCR signaling has not been systematically studied in human pre-B acute lymphoblastic leukemia (ALL).

Goals of the present study were (1) to identify cases of human pre-B ALL with tonic or chronic active pre-BCR signaling, (2) to estimate their frequency, (3) to determine the role of pre-BCR signaling in specific pre-B ALL subtypes, (4) to identify cooperating genetic lesions, and (5) to develop a concept for therapeutic targeting of the pre-BCR pathway in human pre-B ALL.

RESULTS

Expression and Activity of the Pre-BCR Defines a Distinct Subtype of Human ALL

To elucidate pre-BCR expression and function in pre-B ALL cells, we measured expression of the immunoglobulin μ heavy

chain (μ HC) and the pre-BCR surrogate light-chain components λ 5 (IGLL1) and VpreB on a series of 31 patient-derived pre-B ALL xenograft samples and 15 ALL cell lines by flow cytometry (Tables S1–S3). Twenty eight of the 46 pre-B ALL samples and cell lines tested lacked surface pre-BCR expression, including 5 *MLL*-rearranged (*MLLr*), 16 *BCR-ABL1*, 2 *ETV6-RUNX1*, and 5 ALL with other abnormalities. Of the 18 pre-BCR⁺ ALL cases, 14 harbored a *PBX1* gene rearrangement (1q23), 1 carried a deletion at 6q21, 1 carried both *PBX1* gene rearrangement and 6q21 deletion, and 2 harbored *PDGFRB* gene rearrangements (Figures 1A, 1B, and S1A–S1I). Engagement of the pre-BCR using μ HC-specific antibodies resulted in strong Ca^{2+} mobilization from cytoplasmic stores in all 7 pre-BCR⁺ ALL cases tested but not in any of the 19 other cases (Figures 1C and S1A–S1I). These findings suggest that most cases of human ALL lack pre-BCR signaling (pre-BCR⁻), whereas a distinct ALL subgroup (pre-BCR⁺) exists that is defined by pre-BCR expression and activity. Indeed, key components of the pre-BCR signaling, including SRC family kinases (LYN, BLK), SYK, BTK, and PLC γ 2 were constitutively active in six pre-BCR⁺ ALL samples (Figure 1D). Interestingly, phosphorylation of these molecules was sensitive to treatment of the dual ABL1/SRC-BTK inhibitor Dasatinib (Figure 1D).

Tonic Pre-BCR Signaling, Including Activation of SRC, SYK, and PI3K, in a Subset of Human ALL

To compare baseline signaling activity of pre-BCR⁻ and pre-BCR⁺ ALL cells in a large cohort of patients (MDACC 1983–2007, $n = 208$), we divided patient samples into two groups based on flow cytometry measurements of pre-BCR (μ HC) expression and the Ig α signaling chain CD79A (Figure S1J). None of the pre-BCR⁺ ALL cases in this cohort ($n = 26$) expressed the stem/progenitor cell antigen CD34 and CD25, which are both expressed on the surface of most of the 182 pre-BCR⁻ ALL cases (Figure S1K). Using a panel of 133 validated antibodies, we interrogated those 208 pre-B ALL samples at the time of diagnosis for expression and activity of 66 signaling molecules on reverse phase protein arrays (RPPAs) (Tibes et al., 2006). RPPA analyses revealed that pre-BCR⁺ ALL cells exhibit significantly higher expression and activity of SRC family kinases, including LYN, and strong constitutive activity of multiple components of the PI3K-AKT pathway, including PIK3R1 (p85 α), PIK3CD (p110 δ), AKT1-pS⁴⁷³/T³⁰⁸, MTOR-pS²⁴⁴⁸, RPS6KB-pS³⁷¹, and RPS6-pS²³⁵/S²³⁶ (Figures 1E and S1L). Consistent with strong PI3K-AKT signaling, expression and activity of PTEN, a negative regulator of PI3K-AKT signaling, are low in pre-BCR⁺ ALL cells. These findings are consistent with the established central role of SRC/LYN kinase (Saijo et al., 2003) and PI3K-AKT signaling (Srinivasan et al., 2009), in particular PIK3d (Ramadani et al., 2010), in tonic pre-BCR signaling. Pre-BCR⁺ ALL cases are also distinct from pre-BCR⁻ ALL cases by particularly low levels of STAT5 expression and activity (Figure S1L). We conclude that pre-BCR⁺ ALL cells are defined by

(D) Patient-derived Pre-BCR⁺ ALL cells were treated with or without Dasatinib (25 μ Mol/l, 24 hr). Phosphorylation of SRC, BLK, SYK, BTK, and PLC γ 2 was measured by western blot.

(E) Protein expression and phosphorylation levels of LYN, SRC, PIK3R1 (p85), PIK3CD (p110 δ), and AKT were measured by RPPAs in pre-BCR⁺ versus pre-BCR⁻ ALL patient samples (MDACC 1983–2007, $n = 208$). y axis shows \log_2 expression values of RPPA data; p values were calculated from two-sided Wilcoxon test. a distinct signaling phenotype, including constitutive SRC and PI3K-AKT signaling and lack of STAT5 activity.

Tonic Pre-BCR Signaling Is Associated with a Distinct Gene Expression Profile in Human ALL

Upregulation of tonic pre-BCR signaling at the expense of STAT5 in pre-B ALL is reminiscent of negative regulation of IL7R/STAT5 upon pre-BCR activation during normal early B cell development (Ochiai et al., 2012). The shift from IL7R/STAT5 to pre-BCR signaling during early B cell differentiation triggers profound gene expression changes. Therefore, we analyzed the gene expression data from three pre-B ALL clinical trials for children (COG P9906, n = 207; Harvey et al., 2010; and St. Jude Research Hospital, n = 132; Ross et al., 2003) and adults (ECOG E2993, n = 191; Geng et al., 2012). Patients in these trials were classified as pre-BCR⁻ or pre-BCR⁺ based on pre-BCR expression (*IGLL1*, *IGLL3*, *VPREB1*, *VPREB3*, *IGHM*) and its associated signaling molecules *SYK* and *ZAP70* (Figures 2A–2C). To identify a common gene expression signature for pre-BCR⁺ ALL, we performed a supervised analysis of the microarray data and identified a set of 40 genes concordantly differentially expressed in pre-BCR⁺ versus pre-BCR⁻ ALL in all three clinical cohorts (Figures 2A–2C). The upregulated genes include pre-BCR signaling molecules (*PRKCZ*, *BLNK*, *BLK*, *LYN*, *MERTK*, *ROR1*) and transcription factors that promote B cell differentiation (*BCL6*, *BACH2*, *IRF4*, *TCF3*, *POU2AF1*). Downregulated genes include *IL2RA* (CD25) and CD34, confirming flow cytometry data from the MDACC cohort (Figure S1K), the STAT5 target genes (*ID2*, *CD69*, *CD99*, *ITGA6*, *CCND2*, *SOCS2*) and *PRDM1* (BLIMP1) (Figures 2A–2C).

Frequent Rearrangement of PBX1 in pre-BCR⁺ ALL

We studied the coding capacity of immunoglobulin heavy-chain V_HDJ_H gene rearrangements in 152 primary pre-B ALL samples and normal B cell precursors as reference (Trageser et al., 2009). Human bone marrow pro-B, pre-B, and immature B cells from healthy donors (n = 2) were studied by single-cell PCR. In marked contrast to other pre-B ALL subsets, most cases with *TCF3-PBX1* rearrangement and/or 6q21 deletion carried productively rearranged *IGHM* alleles and showed evidence of selection for expression of in-frame V_HDJ_H gene rearrangements, like normal pre-B cells (Figures 2D and 2E; Table S4). In contrast, productive V_HDJ_H gene rearrangements were negatively selected in all other ALL subsets. Combining data from four clinical trials (n = 830; Table S5), we collectively found evidence of pre-BCR function in 112 cases (13.5%). In agreement with a recent study by others and us (Bicocca et al., 2012), pre-BCR expression was frequent among ALL cases with *PBX1* rearrangement or duplication and 6q21 deletion, but rare or absent in cases with *MLLr*, *BCR-ABL1*, *ETV6-RUNX1*, and hyperdiploid ALL (Figure 2F; Tables S5 and S6).

TCF3-PBX1 Binds to and Upregulates Pre-BCR Genes in Human ALL Cells

PBX1 is a proto-oncogene with a critical role in hematopoiesis and lymphopoiesis (Sanyal et al., 2007). In pre-B ALL, *PBX1* (1q23) is frequently rearranged to the B cell-specific *TCF3* (19p13) locus, encoding E2A (E12 and E47) transcription factors. In these cases, the N-terminal transcriptional activation domains of *TCF3* (exons 1–16, *TCF3^N*) are fused to the C-terminal Hox

cooperative motif and homeodomain of *PBX1* (exons 4–9, *PBX1^C*) (Nourse et al., 1990). To identify targets of oncogenic *TCF3-PBX1* activity, we performed chromatin immunoprecipitation (ChIP), followed by massively parallel DNA sequencing (ChIPseq), using antibodies against the *PBX1^C*, the *TCF3^N*, and the *TCF3-PBX1* co-activator p300 (Bayly et al., 2004) in a *TCF3-PBX1* ALL cell line (697) and a primary *TCF3-PBX1* ALL sample (ICN12) (Figure S2A). ChIPseq data revealed that *TCF3-PBX1*, in concert with its coactivator p300, strongly bound to promoter regions of genes that encode key components of the pre-BCR, including *IGLL1*, *VPREB1*, *VPREB3*, *CD79A*, and *CD79B*, as well as μ HC enhancer regions (Figure 3A). Specific binding of *TCF3-PBX1* to these six loci was confirmed by single-locus quantitative ChIP (qChIP), using the fusion-specific *TCF3-PBX1*-hf (Figures 3B and S2B) and the *TCF3^N*, *PBX1^C*, and p300 antibodies (Figures S2C–S2F). To identify genome-wide target genes that are directly regulated by *TCF3-PBX1*, we matched *TCF3-PBX1* binding (ChIPseq; Figure S2D–S2F) with specific gene expression changes that distinguish *TCF3-PBX1* cases from other pre-B ALL subsets (Ross et al., 2003). Among the 1,343 *TCF3-PBX1* (*PBX1^C*, *TCF3^N* and p300) target genes in promoter regions (within 2-kb distance from transcription start site), 99 were specifically upregulated, including multiple pre-BCR components (*IGLL1*, *VREB1*, *VREB3*, *IGHM*) and pre-BCR downstream signaling molecules (*BLK*, *LCK*, *SYK*, *ZAP70*, *PIK3CD*, *PIK3R1*). In addition, 111 targets were significantly downregulated in *TCF3-PBX1* compared to other pre-B ALL subtypes, including the STAT5 target genes *CD69* and *SOCS2* (Figures 3C and 3D). A pathway analysis of *TCF3-PBX1* ChIPseq/gene expression targets suggested that *TCF3-PBX1* is a positive regulator of B cell development and BCR signaling and negatively regulated STAT5 (Figure 3E).

To further test whether gene rearrangement and oncogenic activation of *TCF3-PBX1* induces pre-BCR activity, we studied full-blown ALL populations that had developed after latencies of 90–180 days in the bone marrow from the *TCF3-PBX1*-, *BCR-ABL1*-, and *MLL-AF4*-transgenic mice. Flow cytometry of surface μ HC and CD79B (Ig β) expression confirmed that ALL cells developing in *TCF3-PBX1*-transgenic mice are characterized by pre-BCR expression in contrast to pre-BCR⁻ ALL in *BCR-ABL1*- and *MLL-AF4*-transgenic mice (Figure 3F).

Pre-BCR Signaling Regulates the Balance between BCL6 and STAT5 Activity in Human ALL

Studying gene expression changes in 516 ALL cases from three clinical trials (St Jude, COG P9906, ECOG E2993; Table S5), we found that pre-BCR⁺ ALL cells (n = 71, 13.8%) exhibit consistently higher expression levels of *BCL6* than pre-BCR⁻ cases (n = 445, 86.2%; Figures 2A–2C). Quantitative RT-PCR analyses confirmed 6- to 30-fold higher mRNA and protein levels of *BCL6* in *TCF3-PBX1* ALL compared with other ALL subsets (Figures 4A and S3A). These findings suggested that *BCL6* may be a direct target of *TCF3-PBX1* and other oncogenic transcription factors that drive pre-BCR⁺ ALL. However, ChIPseq and qChIP analysis showed no evidence of binding of *TCF3-PBX1* to the *BCL6* locus (Figures S3B and S3C), indicating that *TCF3-PBX1* induces *BCL6* expression through an indirect mechanism.

Recent studies by us and others (Duy et al., 2010; Swaminathan et al., 2013) revealed a critical role of *BCL6* as a survival

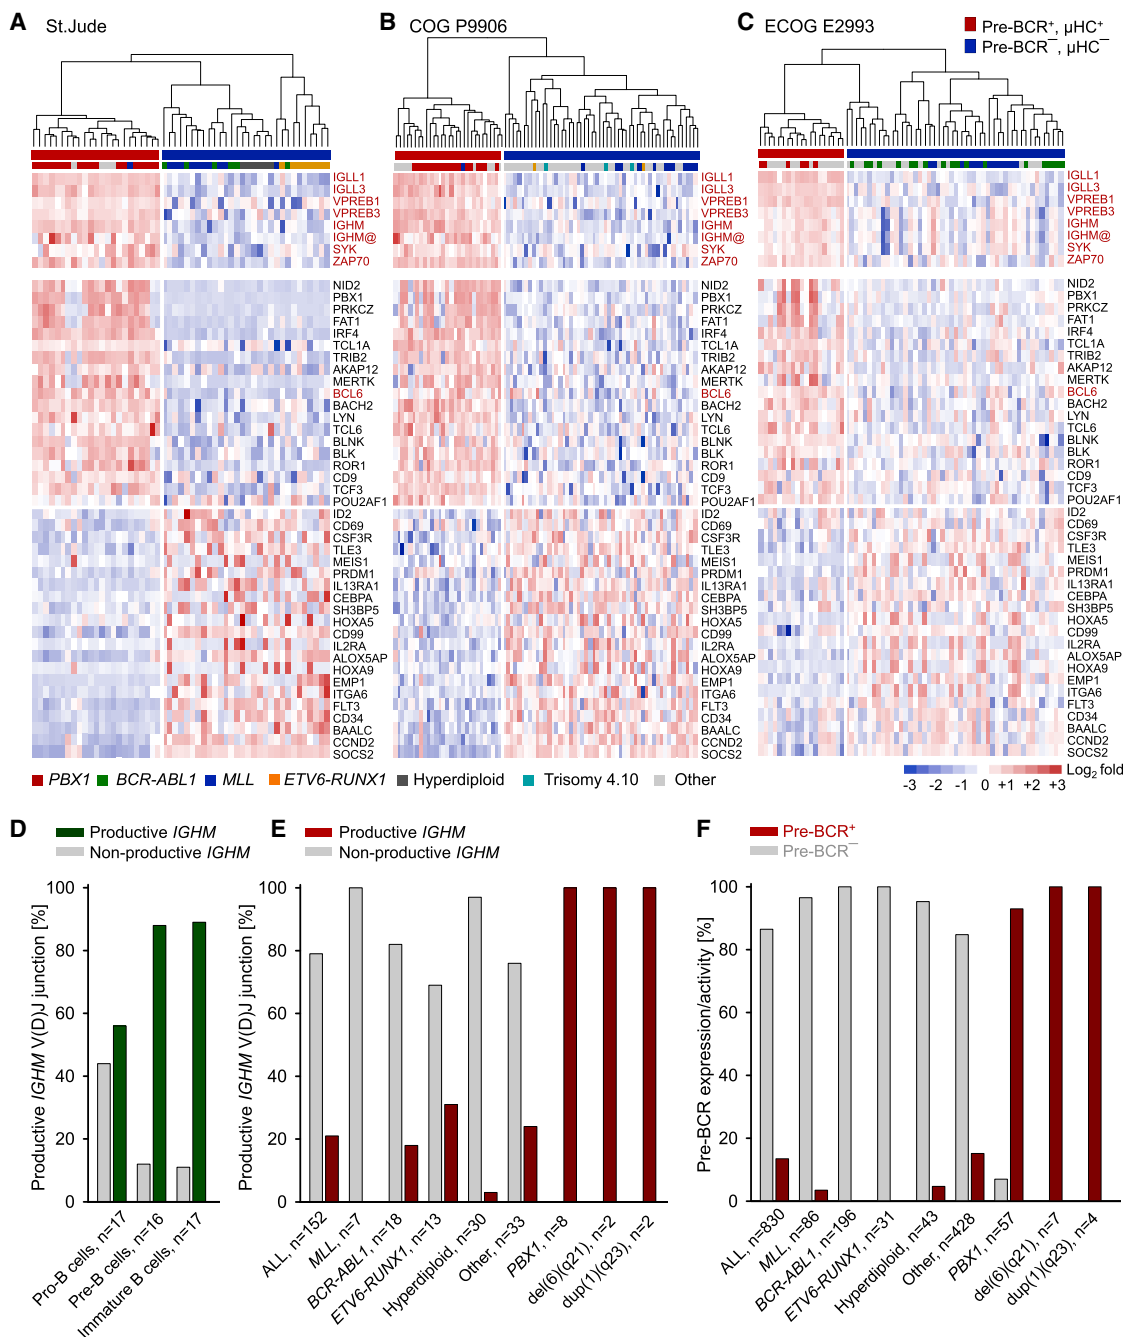

Figure 2. Pre-BCR Signaling in ALL Is Associated with a Distinct Gene Expression and Signal Transduction Phenotype

(A–C) Gene expression microarray data was analyzed from three cohorts of pre-B ALL patient samples for children (St. Jude Research Hospital; COG P9906) and adults (ECOG E2993). In each dataset, the patient samples were ranked based on their average mRNA expression levels of pre-BCR molecules (*IGLL1*, *IGLL3*, *VPREB1*, *VPREB3*, *IGHM*, *SYK*, and *ZAP70*). The top 15% and the bottom 25% cases were considered as the pre-BCR⁺ and pre-BCR⁻ and subject to the clustering analysis. Supervised analysis on pre-BCR⁺ versus pre-BCR⁻ ALL revealed a 40-gene expression signature that is significantly upregulated or downregulated across all three cohorts. The color scale bar represents the relative log₂ expression changes.

(D) The configuration of the μ HC locus (*IGHM*) was studied in human bone marrow pro-B, pre-B, and immature B cells.

(E) Different subtypes of ALL patient samples (n = 152). The y axis shows frequencies of normal B cells or ALL clones with a functional or a non-functional *IGHM* gene rearrangement in these populations.

(F) Frequency of different cytogenetic subtypes of pre-B ALL cases as pre-BCR⁺ or pre-BCR⁻ based on four clinical trials (n = 830, MDACC, St. Jude, COG and ECOG).

See also Tables S4–S6.

Figure 3. TCF3-PBX1 Fusion Protein Binds to and Upregulates Genes Encoding Pre-BCR Components

(A) ChIP-seq tracks for TCF3^N, PBX1^C, and p300 antibodies versus input in a TCF3-PBX1 ALL line 697 and a primary sample ICN12 on IGLL1, VPREB1, VPREB3, CD79A, and CD79B promoter regions and the IGHM enhancer regions (E μ). Gene models were shown in UCSC genome browser hg18.

(B) QChIP validation using an HA antibody that is specific for the HA-Flag-tagged TCF3-PBX1 fusion or an EV as control. NCAPD2 serves as a negative control gene. Data represent means \pm SEM (n = 3); p values are from t test.

(C) The scatter plot shows the average gene expression values of the TCF3-PBX1-rearranged (x axis) versus the non-TCF3-PBX1-rearranged ALL patient samples (y axis) from the St. Jude dataset on the TCF3-PBX1 target genes (n = 1,343). Blue and red highlighted are the downregulated (n = 111) and upregulated (n = 99) genes (>1.5-fold change).

(legend continued on next page)

factor at the pre-BCR checkpoint during normal B cell development. In *BCR-ABL1* ALL (pre-BCR⁻), inhibition of STAT5 activity by treatment with tyrosine kinase inhibitors induced strong expression of BCL6 (Duy et al., 2011). Likewise, in our western blot analysis, while pre-BCR⁺ (*TCF3-PBX1*) ALL cases expressed high levels of BCL6 in the absence of STAT5 activity, we observed the converse in pre-BCR⁻ (*BCR-ABL1*) ALL cells (Figure 4A). To test whether pre-BCR signaling directly affects the balance between BCL6 and STAT5, we used an inducible system for pre-BCR activation in mouse ALL cells. To this end, *Rag2*^{-/-} mouse ALL cells, lacking the ability of endogenous pre-BCR expression, were engineered to express a prearranged tetracyclin-inducible μ HC, which results in subsequent pre-BCR expression (Trageser et al., 2009). Inducible pre-BCR activation resulted in a massive increase of BCL6 protein levels (40-fold) and concomitant silencing of STAT5 activity (p-Y⁶⁹⁴; Figure 4B). Similarly, complementation of a defective pre-BCR signaling chain in *Blnk*^{-/-} or *Ighm*^{-/-} mouse ALL cells by reconstitution of Blnk or μ HC-expression caused dramatic upregulation of BCL6 at the expense of STAT5 activity (p-Y⁶⁹⁴; Figure 4B). Likewise, Cre-mediated deletion of *Stat5* in *Stat5a/b*^{fl/fl} ALL cells was sufficient to increase BCL6 protein levels (Figure 4C). These experiments provide genetic evidence that the balance between BCL6 and STAT5-activity is directly influenced by pre-BCR signaling and hence suggests that high expression levels of BCL6 represent as a surrogate marker for pre-BCR activity in human ALL cells.

BCL6 Expression Represents a Surrogate Marker for Pre-BCR Activity in Human ALL

Immunohistochemical analyses for expression of the pre-BCR (μ HC) and BCL6 were performed on bone marrow biopsies from 72 ALL patients. These analyses confirmed that all 12 pre-BCR⁺ (μ HC⁺) ALL cases express BCL6 at high levels (Figure S3D; Table S7). These cases carried lesions affecting *PBX1*, through *TCF3-PBX1* and/or gain of 1q23 encompassing *PBX1*. In contrast, 60 other cases lacked both BCL6 and μ HC surface expression (Figure S3E). We next performed double-stainings for BCL6 and μ HC on the same slides, confirming that pre-BCR⁻ ALL cells express neither μ HC nor BCL6. In pre-BCR⁺ ALL cases, virtually all cells expressed both surface μ HC and BCL6 at levels comparable to mature B cell lymphoma carrying *IGH-BCL6* rearrangement (Figure 4D). Bone marrow biopsies from pre-BCR⁺ ALL cases included various degrees of admixtures of normal bone marrow cells that lacked both μ HC and BCL6 expression.

SYK Tyrosine Kinase Signaling Is Required for BCL6 Activation Downstream of Tonic Pre-BCR Signaling

Based on the finding that BCL6 is induced by pre-BCR signaling and is a potential target for drug treatment in pre-BCR⁺ ALL cells, we measured the effects of small molecule inhibitors of proximal pre-BCR tyrosine kinases on BCL6 expression. While 57 of 61

ALL cases with *PBX1*-rearrangement or duplication showed evidence of tonic pre-BCR signaling (Figure 2F; Table S5), we did not find pre-BCR activity in any of 196 cases with *Ph*⁺ ALL (*BCR-ABL1*). Consistent with divergent pre-BCR activity in these subsets, we found that *TCF3-PBX1* but not *BCR-ABL1* fusion oncogenes induced expression of BCL6 in pre-B ALL cells (Figure 4E). Treatment with small molecule tyrosine kinase inhibitors of SYK (PRT062607) and BTK (Ibrutinib) reduced BCL6 expression in pre-BCR⁺ *TCF3-PBX1* ALL cells (Figures 4F and 4G), demonstrating that SYK tyrosine kinase activity is required for BCL6 expression in pre-BCR⁺ ALL cells. While *TCF3-PBX1* induces constitutive BCL6 expression via tonic pre-BCR signaling, *BCR-ABL1* represses BCL6 expression. *Ph*⁺ ALL lack BCL6 expression in the presence of active BCR-ABL1, however, ABL1 tyrosine kinase inhibitors (Nilotinib, Dasatinib) relieve BCR-ABL1/STAT5-mediated repression of BCL6 (Figure 4H). Interestingly, the specific ABL1 kinase inhibitor Nilotinib, which does not affect pre-BCR signaling, has no effect on constitutive BCL6 expression in *TCF3-PBX1* ALL cells. However, the dual ABL1/SRC kinase inhibitor Dasatinib, which inhibits the SRC kinases BLK, LYN, and FYN upstream of SYK, almost entirely abolished BCL6 expression in pre-BCR⁺ *TCF3-PBX1* ALL cells (Figure 4H). These findings reveal that based on divergent functions of pre-BCR/BCL6 signaling human ALL can be divided into two genetically and phenotypically distinct subsets.

We propose that in the majority of ALL cases, the transforming oncogene (e.g., *BCR-ABL1*) mimics constitutive active cytokine signaling via activation of STAT5 and repression of BCL6. In 10%–15% of the cases, oncogenic lesions (e.g., *TCF3-PBX1*; Table S8) result in tonic pre-BCR signaling and activation of BCL6. These differences may reflect different cells of origins of the two subsets. BCR-ABL1 engages IL7R-dependent survival and proliferation signals via STAT5 that are active in pro-B and early pre-B cells (Fraction C); in contrast, activation of pre-BCR signaling (e.g., by *TCF3-PBX1*) in late pre-B cells (Fraction C') suppresses IL7R and cytokine signaling (Ochiai et al., 2012). We propose that the mutually exclusive nature of cytokine receptor/STAT5 and pre-BCR/BCL6 pathways in human ALL reflects distinct developmental origins from early (Fraction C) and late (Fraction C') pre-B cells (Figure 4I). BCL6 ChIPseq analysis revealed that BCL6 and STAT5 binding sites were the most highly enriched DNA elements ($p = 10^{-60}$ for both) associated with BCL6 binding peaks in *TCF3-PBX1* ALL cells (Figure 4I), suggesting that BCL6 and STAT5 may compete for binding to those promoters, which would be consistent with mutual exclusive activity of STAT5 and BCL6 in pre-BCR⁻ and pre-BCR⁺ ALL subtypes, respectively.

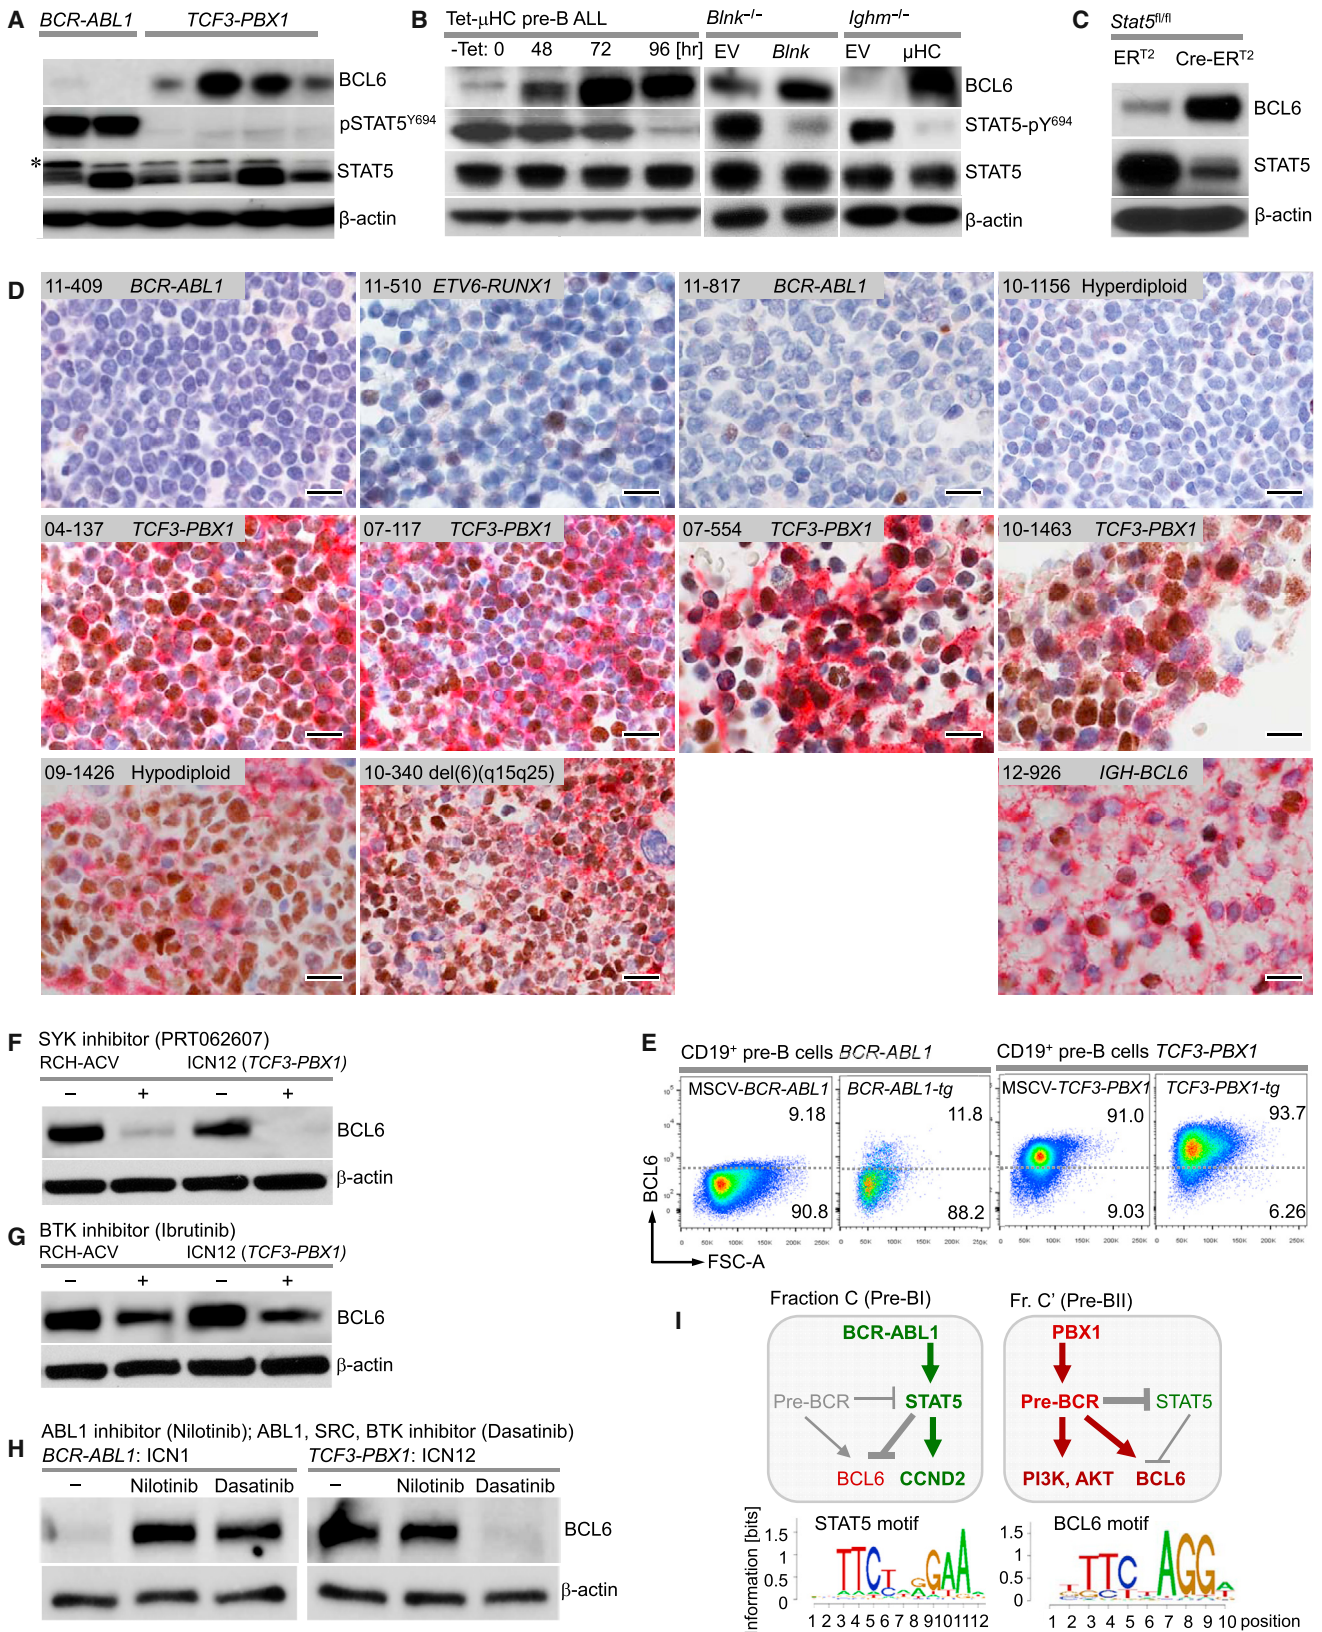

Genetic Mouse Model of Conditional BCL6 Ablation in Pre-BCR⁺ TCF3-PBX1 ALL

BCL6 functions as a classical proto-oncogene in germinal center-derived B cell lymphoma (Ye et al., 1993) and represents a powerful survival factor at the pre-BCR checkpoint during early

(E) Ingenuity pathway analysis for the upregulated and downregulated genes. The color scale indicates p values calculated from Ingenuity.

(F) Flow cytometry staining for cytoplasmic μ HC, surface CD79B, and CD19 in mouse bone marrow CD19⁺ ALL cells transduced with the MLL-ENL, BCR-ABL1, TCF3-PBX1, or EV vector or full-blown ALL populations that had developed after latencies of 90–180 days in the bone marrow from the MLL-AF4-, BCR-ABL1-, or TCF3-PBX1-transgenic mice.

(legend on next page)

B cell development (Duy et al., 2010). For these reasons, we developed a genetic mouse model to determine the role of BCL6 in pre-BCR⁺ ALL cells. In *Bcl6^{fl/fl}-mCherry* mice, exons 5–10 were flanked by *LoxP* sites and Cre-mediated deletion of these exons results in expression of a truncated Bcl6 protein fused to mCherry (Figure 5A). Thereby mCherry expression reflects transcriptional activity of the *Bcl6* promoter and Cre-mediated deletion can be used for inducible ablation of Bcl6 function and as mCherry-based reporter of Bcl6 expression. In a genetic experiment, we transduced *Bcl6^{fl/fl}-mCherry* pre-B cells with *TCF3-PBX1* or an empty vector (EV) control. Cre-mediated deletion (Figure 5B) activated the *Bcl6*-mCherry reporter (Figure 5C). While only ~1% of pre-B cells carrying an EV control showed transcriptional activation of the *Bcl6* promoter, more than 50% of *TCF3-PBX1*-transduced cells actively transcribed *Bcl6* (Figure 5C). These findings demonstrate that *TCF3-PBX1* indirectly induces Bcl6 expression through transcriptional activation of pre-BCR signaling.

BCL6 Transcriptionally Activates Pre-BCR Components in TCF3-PBX1 ALL

To identify BCL6 transcriptional targets in pre-BCR⁺ ALL cells, we performed ChIPseq analysis in patient-derived *TCF3-PBX1* ALL cells (Figures S4A–S4D). As in DLBCL and *Ph⁺* ALL (Duy et al., 2011), BCL6 directly binds to a number of checkpoint molecules, including *RB1*, *CDKN2C*, and *CDKN1B* in pre-BCR⁺ ALL (Figure S4A). A previous study demonstrated that BCL6 increases tonic BCR signaling in DLBCL cells by transcriptional repression of the inhibitory phosphatase *PTPRO* (Juszczynski et al., 2009). Likewise, *PTPRO* was also identified as a transcriptional target of BCL6 in pre-BCR⁺ ALL cells. In addition, BCL6 also binds to pre-BCR components (*IGLL1*, *VPREB1*) and downstream signaling molecules (*BLK*, *BANK1*, *SYK*) (Figure 5D). QChIP validated BCL6 binding to these loci (Figure S4B). To determine how BCL6 binding affects gene expression in *PBX1*-rearranged ALL cells, we measured gene expression changes in response to acute ablation of Bcl6 in a *Bcl6^{fl/fl}-mCherry* mouse model for *TCF3-PBX1* ALL. Upon Cre-mediated deletion of *Bcl6*, multiple BCL6 target genes were de-repressed, including checkpoint molecules *RB1*, *CDKN1A*, *CDKN1B*, *CDKN2A*, and

CDKN2C (Figures 5E and 5F). Also *PTPRO* were among the de-repressed BCL6 target genes, suggesting that BCL6 increases tonic pre-BCR signaling by transcriptional repression of the (pre-)BCR signaling inhibitor *PTPRO* as described in DLBCL (Juszczynski et al., 2009). Interestingly, BCL6 targets with transcriptional activation by Bcl6 include multiple pre-BCR related molecules (*Bank1*, *Syk*; Figures 5E and 5F). To test BCL6-dependent gene regulation in ALL patient samples, we integrated BCL6 ChIPseq target genes with a BCL6-dependent signature of gene expression in 118 cases of childhood pre-B ALL (St. Jude). This analysis showed transcriptional activation of 63 BCL6 target genes, including multiple pre-BCR related molecules (*IGLL1*, *BLK*, *VPREB1*, *PIK3CD*, *SYK*; Figures 5G and 5H). Collectively, these findings suggest a self-enforcing activation loop between tonic pre-BCR signaling and BCL6 activity in a subset of human ALL: oncogenic activation of tonic pre-BCR signaling (e.g., as a result of *PBX1* rearrangement and duplication) induces strong activation of BCL6, which further activates pre-BCR signaling (e.g., through transcriptional repression of *PTPRO* and *PRDM1* and activation of *IGLL1*, *VPREB1*, *BLK*, *SYK*). Interestingly, *PBX1* binding to promoter regions of pre-BCR-related genes frequently co-localizes with binding of BCL6, suggesting that BCL6 and *PBX1* cooperate in the regulation of these genes (Figure 5I).

Pre-BCR⁺ ALL Cells Are Dependent on BCL6 Activity

Pre-BCR⁺ ALL and BCR-dependent B cell lymphoma share constitutively high BCL6 expression levels. To determine whether high expression levels of BCL6 correlate with clinical outcome of ALL patients, we analyzed mRNA levels of *BCL6* at the time of diagnosis in children with high-risk ALL (COG P9906) and adults with ALL (ECOG E2993). Only patients of known pre-BCR expression status were included in the analysis. Since BCL6 was specifically upregulated by tonic pre-BCR signaling, we performed clinical outcome analyses separately for pre-BCR⁺ and pre-BCR⁻ ALL cases. In both the pediatric (COG P9906, $p = 0.043$) and adult (ECOG E2993, $p = 0.013$) clinical trials, higher than median expression levels of BCL6 were predictive of poor outcome among patients with pre-BCR⁺ but not pre-BCR⁻ ALL (Figures 6A and 6B). These findings suggest

Figure 4. Pre-BCR Signaling in ALL Cells Drives Expression of BCL6

(legend on next page)

that high expression levels of BCL6 affect the course of disease in pre-BCR⁺ but not pre-BCR⁻ ALL. To determine the potential contribution of BCL6 signaling to survival and proliferation of pre-BCR⁺ ALL cells, we studied inducible ablation of *Bcl6* in a mouse model (Figures 5A–5C). *Bcl6^{fl/fl} TCF3-PBX1* ALL cells were transduced with 4-hydroxy-tamoxifen (4-OHT)-inducible Cre (Cre-ER^{T2}) or an EV control (ER^{T2}). While 4-OHT mediated deletion of *Bcl6* resulted in progressive depletion of Cre-ER^{T2}-transduced cells, it had no measurable effects in ER^{T2}-transduced *Bcl6^{fl/fl} TCF3-PBX1* ALL cells (Figure 6C). To verify BCL6 dependency of pre-BCR⁺ ALL in a patient-derived setting, we transduced xenografted *TCF3-PBX1* ALL cells with an inducible dominant-negative BCL6 mutant lacking the BCL6-BTB domain (^{DN}BCL6-ER^{T2}) (Shaffer et al., 2000). While the fraction of ICN12 cells carrying ER^{T2} EVs remained stable after 4-OHT treatment, cells transduced with ^{DN}BCL6-ER^{T2} were rapidly depleted (Figure 6D). These findings collectively identify BCL6 as a potential target for the treatment of pre-BCR⁺ ALL.

Pharmacological Inhibition of BCL6 in Pre-BCR⁺ ALL Cells

In a complementary approach, we tested the consequences of shRNA-mediated knockdown of BCL6 in pre-BCR⁺ ALL cells. Upon doxycycline-inducible expression of BCL6-specific shRNAs, we observed moderate reduction of BCL6 protein expression and impaired colony formation capacity in pre-BCR⁺ ALL cells (Figures S5A–S5C). For proof-of-principle experiments, a specific *retro-inverso* BCL6 peptide-inhibitor (RI-BPI) was used to inhibit BCL6 function (Cerchiatti et al., 2009). Treatment of patient-derived pre-BCR⁺ ALL cells with 5 μmol/l RI-BPI induced cell cycle arrest within 1 day of treatment (Figures 6E and S5D) and caused impaired colony formation capacity (Figure S5E). Whereas RI-BPI treatment alone did not induce significant acute toxicity, it strongly sensitized pre-BCR⁺ ALL cells to Vincristine (1 nmol/l, *p* = 0.003; Figures 6F and S5F), a mitotic spindle inhibitor that is part of the chemotherapy backbone in most current clinical trials for ALL. In conclusion, BCL6 represents a predictor of poor clinical outcome and a potential target for therapy of patients with pre-BCR⁺ ALL.

Pre-BCR⁺ and Pre-BCR⁻ ALL Cells Exhibit Distinct Kinase-Inhibitor Sensitivity Profiles

Besides inhibition of BCL6 expression (Figures 4F–4H and S6A), PRT062607 (SYK), Ibrutinib (BTK), and Dasatinib (SRC) induced

selective toxicity in pre-BCR⁺ ALL cells (Figure 7A). Pre-BCR⁺ ALL (*n* = 7), pre-BCR⁻ ALL (*n* = 8), and mature B cell lymphoma cells (*n* = 2) were treated with inhibitors of pre-BCR tyrosine kinases PRT062607 (SYK), Ibrutinib (BTK), Dasatinib (SRC), as well as inhibitors of pre-BCR downstream signaling, including GS-1101 (PI3Kδ), AZD05363 (AKT1), Rapamycin (mTOR), AZD6244 (MEK1), SCH772984 (ERK1, ERK2), Enzastaurin (PKCβ), MI2 (MALT1), and BMS345541 (IKK, NF-κB) (Figure S6B). For treatment with the dual SRC/ABL1 kinase inhibitor Dasatinib, only *Ph⁺* ALL cells expressing mutant *BCR-ABL1^{T315I}* were studied to rule out effects of BCR-ABL1 tyrosine kinase inhibition. Compared with pre-BCR⁻ ALL and mature B cell lymphoma cells, pre-BCR⁺ ALL cells were selectively sensitive to inhibition of SYK and SRC (BLK, LYN) and, to some lesser degree, to inhibition of BTK (Figure 7A) and PI3Kδ (Figure S6B). On the other hand, pre-BCR⁻ ALL cells were selectively sensitive to inhibitors of MEK1 (AZD6244) and ERK1/2 (SCH772984), suggesting that pre-BCR⁺ and pre-BCR⁻ ALL cells can be distinguished based on a specific profile of kinase-inhibitor sensitivity.

To address this possibility in a formal experiment, we treated pre-BCR⁺ (*n* = 8) and pre-BCR⁻ (*n* = 9) ALL cells with a diverse panel of 51 kinase inhibitors that are currently being studied for the treatment of hematological malignancies and solid tumors (Figure 7B). This analysis confirmed that pre-BCR⁺ ALL cells are particularly sensitive to inhibitors of SYK, SRC, and PI3Kδ, whereas pre-BCR⁻ ALL cells are more responsive to inhibition of MEK1 and ERK1/2 (Figure 7B). Integrating experimentally measured sensitivities to individual inhibitors with their known biochemical IC₅₀ values for individual kinase targets, we established a kinase dendrogram of specific vulnerabilities of pre-BCR⁺ and pre-BCR⁻ ALL (Figure 7C). While pre-BCR⁺ ALL cells were most dependent on SYK, ZAP70, BTK, and LYN activity, pre-BCR⁻ ALL cells were most vulnerable to inhibition of ABL1, PDGFR, ERK1, ERK2, MET, and KIT kinase activity (Figure 7C).

Validation of Pre-BCR-BCL6 Signaling as a Therapeutic Target in Pre-BCR⁺ ALL Cells

The usefulness of pre-BCR signaling inhibitors PRT062607 (SYK), Ibrutinib (BTK), and Dasatinib (SRC, BTK) for the treatment of pre-BCR⁺ ALL was tested in a proof-of-principle experiment. To this end, one million patient-derived *TCF3-PBX1* pre-BCR⁺ ALL cells (ICN12) labeled with luciferase were injected

Figure 5. BCL6 Is a Key Regulator of the Transcriptional Program in Pre-BCR⁺ ALL Cells

(A) A genetic model for inducible ablation of *BCL6* and a mCherry-based *Bcl6* reporter (*Bcl6^{fl/fl}-mCherry*). Exons 5–10 of the *Bcl6* locus were targeted for inducible Cre-mediated deletion. *LoxP* sites are indicated as black triangles.

(B) PCR validation of the floxed, deleted, and WT *Bcl6* allele from *Bcl6^{fl/fl}-mCherry* mouse bone marrow pre-B cells.

(C) FACS analysis of EV^{Neo} or *TCF3-PBX1^{Neo}* retrovirally transduced *Bcl6^{fl/fl}-mCherry* pre-B cells that were transduced with either EV^{GFP} or Cre^{GFP} vector for *Bcl6* deletion. y axis indicates mCherry expression, and x axis indicates GFP expression.

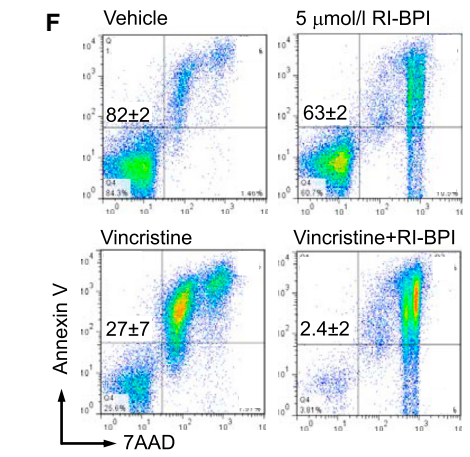

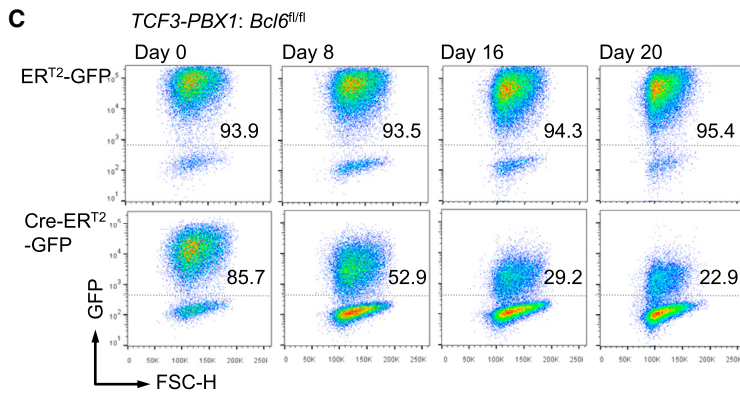

(D) BCL6 ChIPseq binding tracks of target genes in patient-derived *TCF3-PBX1* ALL cells (ICN12). y axis represents the number of reads for peak summit normalized by the total number of reads per track. Gene models are shown in UCSC genome browser hg18. A control intragenic region and BCL6 were used as negative and positive controls.

(E and F) A meta-analysis of BCL6 ChIPseq target genes (*n* = 666) with gene expression microarray data for the EV versus Cre transduced *Bcl6^{fl/fl} TCF3-PBX1* ALL cells.

(G and H) for the BCL6^{High} versus BCL6^{Low} ALL patient samples from St. Jude. The scatter or heat-map plots showed upregulated and downregulated BCL6 target genes in each dataset. The color scale bar represents relative log₂ expression changes.

(legend on next page)

intravenously into sublethally irradiated NOD/SCID mice. Recipient mice were then treated with vehicle ($n = 11$), PRT062607 (100 mg/kg, $n = 7$), Ibrutinib (75 mg/kg, $n = 7$), and Dasatinib (40 mg/kg, $n = 12$). All of the inhibitors were well tolerated and achieved significant reduction of leukemia burden in vivo, as determined by luciferase bioimaging (Figure 8A). These experiments, together with in vitro testing (Figures 7A and 7B), suggested that Dasatinib has the strongest anti-leukemic effect among the three pre-BCR signaling inhibitors. For this reason, we prioritized Dasatinib for detailed in vitro validation experiments for a group of 135 patient-derived ALL samples, including various ALL subtypes but not Ph^+ ALL. Patient-derived ALL cells were cultured over 72 hr in the absence or presence of Dasatinib in concentrations ranging from 1 to 1,000 nmol/l to calculate Dasatinib IC_{50} values for these cases. Our previous kinase inhibitor screening assays (Tyner et al., 2013) showed that the median IC_{50} for Dasatinib of all hematologic malignancy samples received at OHSU ($n > 400$) was 900 nmol/l. Importantly, all 22 pre-BCR⁺ ALL cases were sensitive to Dasatinib ($IC_{50} < 50$ nmol/l). In contrast, only 6 of 113 pre-BCR⁻ ALL cases had $IC_{50} < 50$ nmol/l, and the vast majority of these cases did not respond to Dasatinib at concentrations up to 1,000 nmol/l (Figure 8B). Based on a large dataset from 135 patient-derived ALL samples, we conclude that Dasatinib has strong selective antileukemia effects on pre-BCR⁺ ALL cases. To confirm efficacy of Dasatinib in vivo, we transplanted leukemia cells from four patients with pre-BCR⁺ ALL into sublethally irradiated NOD/SCID mice. Three of these cases carried a *TCF3-PBX1* gene rearrangement, and one case is hypodiploid. In one case (07-112), treatment with Dasatinib alone was sufficient to eradicate ALL and to cure mouse transplant recipients, whereas vehicle-treated mice died within 130 days after injection (Figure 8C). In the three other cases, Dasatinib treatment significantly delayed leukemic expansion and prolonged overall survival of transplant recipient mice. A composite Kaplan-Meier analysis of the four cases injected into a total of 25 mice per group showed a substantial benefit of Dasatinib treatment ($p = 0.0001$; Figure 8C). To monitor expansion of human leukemia cells (expressing human CD19 and CD45) in the recipient mice, peripheral blood from these mice was drawn weekly and analyzed for chimerism. The Dasatinib-treated cohorts showed minimal signs of circulating human chimerism comparing to the untreated cohorts (Figure 8C). These results demonstrate feasibility and efficacy of leukemia clearance in vivo of pre-BCR⁺ ALL by Dasatinib based on four patient-derived samples. We expect that combinations with other pre-BCR signaling inhibitors (e.g., PRT062607, Ibrutinib) may

have synergistic effects, which will be the focus of future studies by our group.

DISCUSSION

Recent analyses revealed that BCR-dependent B cell lymphomas can be divided based on tonic or chronic active BCR signaling (Davis et al., 2010; Rickert, 2013; Schmitz et al., 2012). Tonic BCR signaling involves activation of one single pathway, namely PI3K δ signaling downstream of SRC (LYN, FYN, BLK) and SYK (Burger and Okkenhaug, 2014; Chen et al., 2013) and is associated with germinal center B cell-like (GCB-) DLBCL and Burkitt's lymphoma (Young and Staudt, 2013). On the other hand, chronic active BCR signaling in ABC-DLBCL, CLL and MCL engages multiple downstream pathways including BTK (and its downstream targets PKC β , MALT1, and NF- κ B), calcineurin/NFAT, and MEK/Erk (Young and Staudt, 2013). While the majority of B cell lymphoma cases are BCR dependent and sensitive to BCR signaling antagonists, classical Hodgkin's lymphoma (Kanzler et al., 1996), and primary mediastinal B cell lymphoma (PMBL) (Leithäuser et al., 2001) together account for 15%–20% of human B cell lymphoma and lack BCR function. The classification of B cell lymphoma based on (1) chronic active, (2) tonic, and (3) lack of BCR signaling informed the development of new treatment strategies and has led to the successful introduction of BTK (chronic active) (Byrd et al., 2013a, 2013b; Wang et al., 2011) and PI3K δ (tonic BCR signaling) inhibitors (Gopal et al., 2014) into patient care.

Like mature B cell lymphoma, pre-B ALL originates from B cell precursors that critically depend on survival signals emanating from a functional (pre-)BCR. In contrast to B cell lymphoma, however, a classification of human ALL based on pre-BCR function and activity is not available. Studying 830 ALL cases from four clinical trials, we found no functional equivalent of chronic active BCR signaling in B cell lymphoma. In the majority of ALL cases, ALL cells lacked pre-BCR signaling (pre-BCR⁻), a functional equivalent to classical Hodgkin's lymphoma and PMBL among mature B cell malignancies. However, in about 13.5% of human ALL cases, ALL cells expressed a functional pre-BCR (pre-BCR⁺) and were highly sensitive to inhibition of SYK and SRC kinases and relatively resistant to inhibition of PKC β , MALT1, and IKK/NF- κ B.

Unlike ABC-DLBCL (chronic active BCR signaling), GCB-DLBCL express high levels of BCL6 in the context of tonic BCR signaling (Juszczynski et al., 2009). Here we found constitutive and pre-BCR-dependent expression of BCL6 in all pre-BCR⁺ ALL cases studied. Conversely, as a marker in

Figure 6. Pre-BCR⁺ ALL Cells Are Dependent on BCL6 Activity

(A and B) Patients were segregated into two groups based on higher or lower than the median expression of BCL6 in pre-BCR⁺ and pre-BCR⁻ ALL in two clinical trials: (A) COG P9906 and (B) ECOG E2993. Kaplan-Myer estimates were used to plot the survival probabilities; p values were calculated from the log-rank test. (C) *Bcl6^{fl/fl} TCF3-PBX1* pre-B ALL cells were transduced with 4-OHT-inducible Cre (Cre-ER^{T2}-GFP) or EV control (ER^{T2}-GFP). Percentage of GFP-positive cells was measured by flow cytometry at different time points following 4-OHT treatment, and time course data are depicted. (D) Patient-derived Pre-BCR⁺ ALL cells (ICN12) were transduced with 4-OHT-inducible dominant-negative BCL6 (^{DN}BCL6-ER^{T2}-GFP) or EV control (ER^{T2}-GFP). Percentages of GFP-positive cells were measured by the flow cytometry at different time points following 4-OHT treatment. (E) ICN12 cells were treated with vehicle or 5 μ mol/l RI-BPI for 24 hr and then subjected to cell-cycle analysis (BrdU and 7-AAD staining). (F) ICN12 cells were exposed to vehicle, Vincristine (1 nmol/l), RI-BPI (5 μ mol/l), or combination of Vincristine (1 nmol/l) and RI-BPI (5 μ mol/l) for 3 days, followed by flow cytometry for Annexin V and 7-AAD staining. Data represent means \pm SEM ($n = 3$); p values from t test. See also Figure S5.

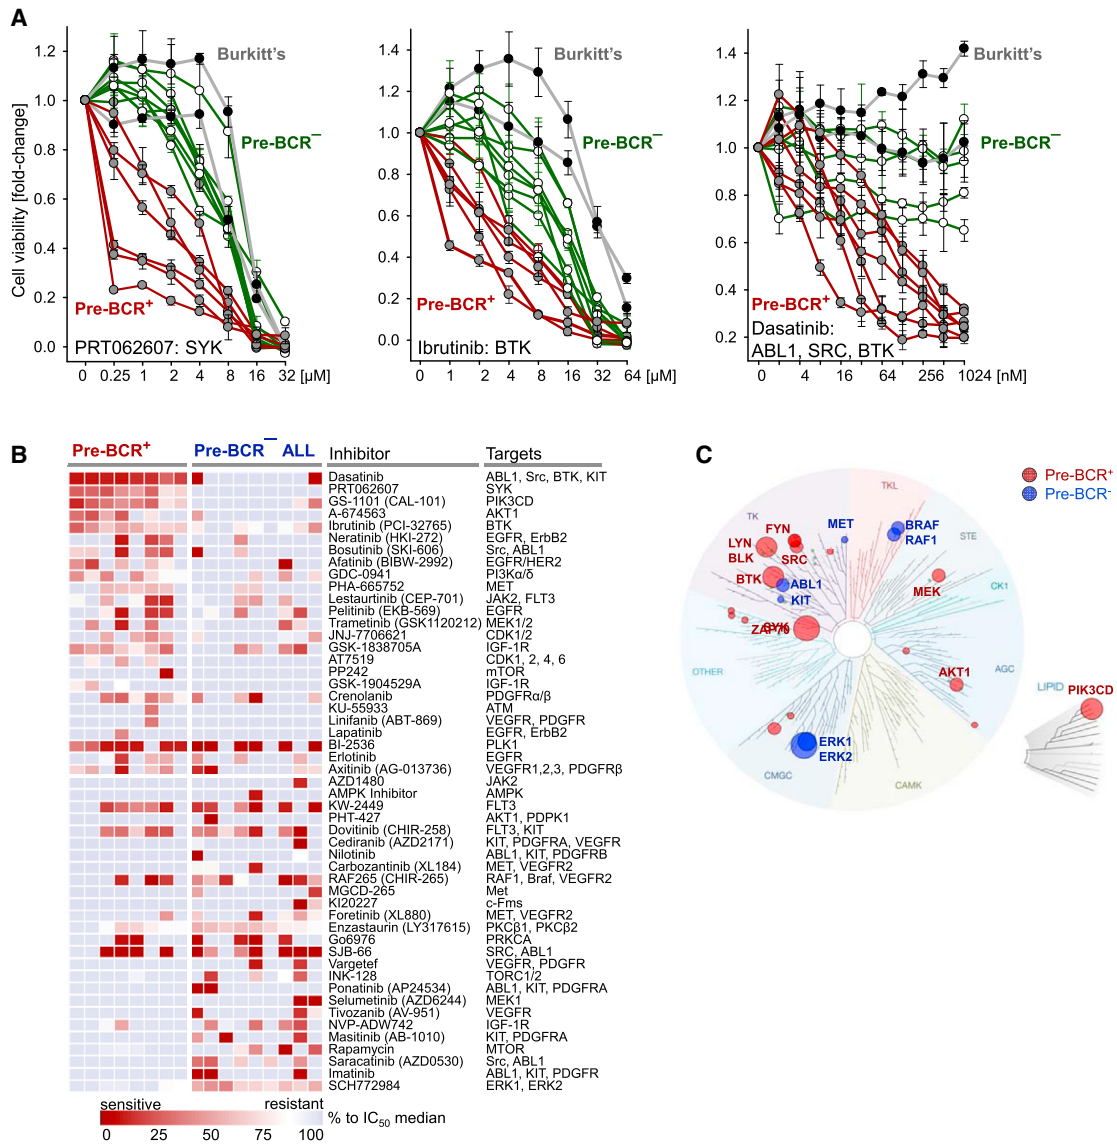

Figure 7. Validation of Pharmacological Inhibition of BCL6-Pre-BCR Signaling as Therapeutic Target in Pre-BCR⁺ ALL Cells

(A) Cell viability was measured using CCK-8 in presence or absence of PRT062607 (SYK), Ibrutinib (BTK), or Dasatinib (ABL1/SRC/BTK) for 72 hr with gradients of concentrations as indicated in the x axis in pre-BCR⁺ ALL (n = 7), pre-BCR⁻ ALL (n = 8) and 2 Burkitt lymphoma (MN60, MHH-preB). y axis shows the percentage of viable cells with the untreated cells as control (set to 100%). Data represent means ± SD (n = 3).

(B) Pre-BCR⁺ (n = 8) and pre-BCR⁻ (n = 9) patient-derived ALL samples were treated with a diverse panel of 51 kinase inhibitors as described previously (Tyner et al., 2013). The heat map represents the IC₅₀ values for each sample relative to the observed median IC₅₀ value for over 400 primary leukemia samples interrogated by this assay at OHSU. Red or blue colors denote higher or lower than the median sensitivity of the pre-B ALL cells tested. Pre-BCR⁺ ALL: 07-112, 11-064, ICN12, 697, RCH-ACV, Kasumi-2, HPB null, Nalm6. Pre-BCR⁻ ALL: BV173, SUPB15, BLQ5, LAX2, SEM, RS4;11, REH, LAX7R, SFO3.

(C) Kinase dendrogram of pre-BCR⁺ and pre-BCR⁻ ALL based on experimentally measured sensitivities to individual inhibitors and their known inhibitory profile based on biochemical IC₅₀ values for individual kinase targets. TREESpots software was used (KINOMEScan, <http://www.discoverx.com/home>).

See also Figure S6.

immunohistochemistry staining, BCL6 reliably identified pre-BCR⁺ ALL cases. BCL6 expression is indeed dependent on tonic pre-BCR signaling, as small molecule inhibition of SYK and SRC family kinases abolished BCL6 expression in pre-BCR⁺ ALL cells. Since functional assays to measure tonic pre-BCR signaling in ALL patient samples may not be practical for diagnostic purposes, we propose that BCL6 and μHC immunostaining may be a feasible alternative to rapidly identify patients that

might benefit from treatment with inhibitors of tonic pre-BCR signaling (e.g., SYK, SRC, PIK3δ).

EXPERIMENTAL PROCEDURES

Primary Human Samples and Cell Lines

After informed consent from all participants, primary ALL cases were obtained with the approval of the Institutional Review Boards of the University of

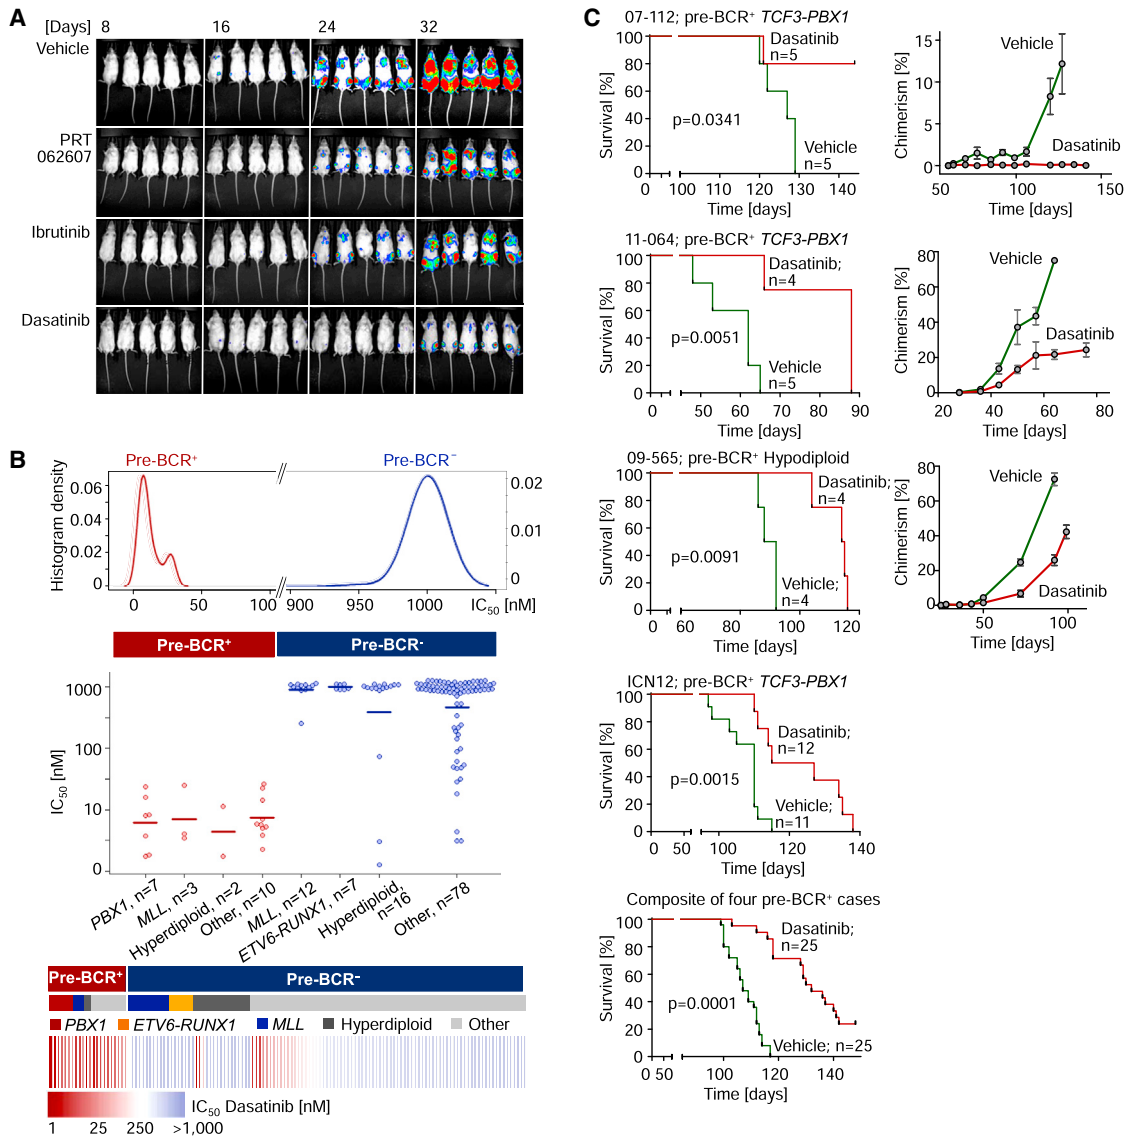

Figure 8. Validation of Pharmacological Inhibition of BCL6-Pre-BCR Signaling in Patient-Derived Pre-BCR⁺ ALL Cells

(A) Patient-derived pre-BCR⁺ ALL cells (ICN12) were labeled with luciferase and 1-million cells were injected intravenously to sublethally irradiated NOD/SCID mice. The mice were randomly separated into four groups and treated with vehicle, the SYK inhibitor PRT062607 (100 mg/kg), the BTK inhibitor Ibrutinib (75 mg/kg), or Dasatinib (40 mg/kg) respectively. Bioimages were taken at different time points for each of the groups.

(B) Plot of Dasatinib IC₅₀s from primary ALL patient samples (n = 135, OHSU). ALL samples were cultured over 72 hr in the presence or absence of Dasatinib in concentrations ranging from 1 to 1,000 nmol/l to calculate the IC₅₀ values.

(C) Patient-derived pre-BCR⁺ ALL cells (n = 4) were injected to sublethally irradiated NOD/SCID mice. Mice were treated with vehicle or Dasatinib (40–50 mg/kg). Kaplan-Meier estimates were used to plot the survival probabilities for each treatment group versus vehicle control; p values were calculated from log-rank test. Peripheral blood was drawn weekly and analyzed for chimerism with either human CD19 or human CD45 versus murine CD45 and plotted over time. Data represent means ± SD (n = 4 or 5).

California San Francisco (UCSF) and Oregon Health and Science University (OHSU). Primary human ALL samples were cultured on OP9 stroma in minimum essential medium (MEM α ; Life Technologies) with GlutaMAX containing 20% fetal bovine serum (FBS), 100-IU ml⁻¹ penicillin, 100- μ g ml⁻¹ streptomycin, and 1-mM sodium pyruvate at 37°C in a humidified incubator with 5% CO₂. The human cell lines were purchased from DSMZ. See Tables S1–S3.

In Vivo Leukemia Cell Transplantation and Treatment

All mouse experiments were subject to institutional approval by the University of California San Francisco Institutional Animal Care and Use Committee; 10⁶ cells from primary *TCF3-PBX1* pre-BCR⁺ ALL were inocu-

lated via intravenous injection into sublethally irradiated (250 cGy) adult female NOD/SCID mice (n = 37). After injection of leukemia cells, the mice were randomly separated into four groups and treated with (1) Dasatinib (40 mg/kg, n = 12), (2) Ibrutinib (75 mg/kg, n = 7), (3) PRT062607 (100 mg/kg, n = 7), and (4) vehicle (n = 11). Leukemic infiltration was confirmed by flow cytometry and bioimaging.

Statistical Analysis

The Kaplan-Meier method was used to estimate overall survival. Log-rank test was used to compare survival differences between patient groups. The R package “survival” v.2.35-8 was used for the survival analysis.

ACCESSION NUMBERS

The gene expression microarray and ChIPseq data reported in this paper have been deposited in the NCBI Gene Expression Omnibus (GEO) (<http://www.ncbi.nlm.nih.gov/geo>) database with the GEO accession numbers GSE59332 and GSE59538.

SUPPLEMENTAL INFORMATION

Supplemental Information includes Supplemental Experimental Procedures, six figures, and eight tables and can be found with this article online at <http://dx.doi.org/10.1016/j.ccell.2015.02.003>.

H.G., A.D., S.M.K., E.P., A.M., S.P.H., M.L.L., and B.H.C. provided and characterized patient samples and clinical outcome data. J.J.B., B.H.Y., K.M.A., A.M., J.A.B., R.G.R., and M.M. provided important reagents and mouse samples. M.M. and B.H. designed experiments and conceived the study. M.M. wrote the paper.

ACKNOWLEDGMENTS

We thank Michael L. Cleary (Stanford) for critical discussions, Arthur L. Shaffer and Louis M Staudt for inducible BCL6 constructs, Mark Kamps and David B. Sykes for inducible *TCF3-PBX1* vectors, Lothar Hennighausen for *Stat5ab^{fl/fl}* mice, and Julia Gastier-Foster and I-Ming Chen for fresh samples from the COG ALL Biology Bank (proposal number 2008-08). This work is supported by grants from the NIH/NCI through R01CA137060, R01CA139032, R01CA157644, R01CA169458, R01CA172558 (to M.M.), CA178765 and CA163068 (to R.G.R.), R00CA151457 and R01CA183947 (to J.W.T.), U10 CA98543 (COG Chair's grant), U10 CA98413 (COG Statistical Center), and U24 CA114766 (COG Specimen Banking), the Hyundai Hope on Wheels, the St. Baldrick's Foundation, the Leukemia & Lymphoma Society Specialized Center of Research (LLS SCOR) and Tucker's Toy Box Foundation (to B.H.C.), the William Lawrence and Blanche Hughes Foundation, the California Institute for Regenerative Medicine (CIRM; TR2-01816), Leukaemia and Lymphoma Research (to M.M.), the Medical Research Council and the National Institute for Health Research Oxford Biomedical Research Centre Program (to T.M. and E.B.). B.J.D. is supported by the Howard Hughes Medical Institute. M.M. is a Scholar of the Leukemia and Lymphoma Society and a Senior Investigator of the Wellcome Trust.
